Statistica Inference

Linear regression models

Logit model:

- You should have defined a project (working directory) somewhere in your computer (e.g., Desktop).
- R is the actual programming language
- RStudio is an IDE (Integrated Development Environment) for R.
- R is case sensitive; e. g., Mean \neq mean
- R(Studio) may not work very well when files (or directory containing working files) have accented characters. If the locale language of your filesystem is not in English, then some errors may occur in those cases.

Basic calculations

Introduction to R

Statistica Inference

Linear regression models

Logit models

Timo carios

- R can be used as a calculator
- Mathematical constants:
 - pi = 3.142
 - $\exp(1) = 2.718$
- Logarithms:
 - log(e) = 1
 - $\log 10(100) = 2$
 - log(16, base = 4) = 2

Display Information

Linear regression models

Logit models

Time series

One of the strengths of R is the increasing number of available packages (more than 14,000 of them): CRAN Packages

To install and use a package we have

- firstly to install it;
- then, to load it in the current session.

To install a package (e.g., tseries), we can use the install.packages("tseries") function.

To load it in the current session, use library(tseries)

To install a package, we can also use the Tools option in the RStudio window and follow Install Packages...

Linear regression models

Logit models

Timo carios

The data types used by R are

- numeric (double precision): 2.718, 1.4, ...
- integer: 1, −13, . . .
- complex: 2 − 3*i*, . . .
- logical: TRUE, FALSE. Also NA is considered logical
- character: "one plus two", "Hello world!"

Data Structure

Introduction to R

Introduction to R(Studio

Data Types and Data Structure

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regressior models

Logit model

- Vector: basic data structure in R. Its components have the same data type.
- Matrix: think of linear algebra.
 - A matrix as a collection of vectors.
- Dataframe: similar to a matrix, except that it is not necessarily homogeneous.
 - A collection of vectors (of possible different types) with the same length.
- List: generic data structure containing other objects (vectors, other lists), not necessarily of the same length.

Assignment operator

Introduction to R

Introduction to R(Studio

Data Types and Data Structure

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

- In R, we assign a value, value, to an object x by means of
 x <- value
- To type it, you can use the shortcut ALT+"-" (ALT key and minus sign); it works with Windows, MacOS.
- It is also possible to use =, but the equal sign has lower priority than <-.
 - Check the discussion at StackExchange.

Vectors

Introduction to R

Lino AA Notarantonio (lino@tec.mx)

Introduction to R(Studio

Data Types and Data Structure

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regressior models

Logit models

Time series

The easiest way to create a vector in R is to use the c() (concatenate) function:

$$v \leftarrow c(1, 3, 5, 7, 9)$$

V

Vectors: coercion

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regressior models

Logit models

Time series

Consider the vector

$$x < -1:100$$

Then,

- $x^2 = 1$, 4, 9, 16, 25, 36 ...
- 2*x+3 = 5, 7, 9, 11, 13, 15 ...
- sqrt(x) = 1, 1.414, 1.732, 2, 2.236, 2.449 ...

Vectorization

Introduction to R

Lino AA Notarantonio (lino@tec.mx)

Data Types and Data Structure

We can add up two vectors even when they have different lengths, provided that the length of one is an integer multiple of the other:

```
x < - seq(1,11,2)
y < -1:12
x + y
```

[1] 2 5 8 11 14 17 8 11 14 17 20 23 ##

```
Check for identity
```

```
all(x + y == rep(x,2) + y)
## [1] TRUE
identical(x + y, rep(x,2) + y)
## [1] TRUE
```

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Timo carios

Selection

$$y \leftarrow c(1, -2, 4, 6, 9, 2, 1)$$

- which(y <= 4): 1, 2, 3, 6, 7
 selects which entries satisfy the condition. Indexing of vectors starts from 1.
- y[which(y <= 4)]: 1, -2, 4, 2, 1 returns the values of the entries satisfying the condition.
- which(y == max(y)): 5 entry of the vector with the maximum value
- y[which(y == max(y))]: 9
 maximum value of the vector

Matrices

Introduction to R

Time series

The operator **%*%**

The operator **%*%** works differently on vectors and matrices.

- On vectors it computes the dot product
- On matrices, the matrix multiplication (matrix multiplication is a form of ordered, vectorized dot product)

```
a \leftarrow c(1,2,3)
```

$$b \leftarrow c(4,5,6)$$

The dot product can also be implemented as

```
sum(a*b)
```

Timo sorios

- Statistical analysis is done using datasets. A dataset contains a certain number of variables and observations.
- It is a good practice to have each variable set as a column vector and each observation as a row vector.
- A dataframe, in R, is the data structure of an observed dataset.
- A dataframe can be thought of as a matrix in which different columns may have different data types.

When loading a dataset for analysis, there are some aspects to consider.

- Understand the data: what the dataset is about; what are its variables; how many obervation the dataset contains.
- Oetermine whether there are missing observations; some functions will not work properly otherwise.
- Visualize some of its variables.

Import the dataset with RStudio

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Time series

Examples

• Compute the number of individuals whose age is greater than, or equal to, 50 years:

```
length(cleve$age[cleve$age >= 50])
```

```
## [1] 216
```

2 Compute the number of individuals without a diagnosis of heart disease:

```
length(cleve$sex[cleve$diagnostic == 0])
```

```
## [1] 164
```

Remark The variable diagnostic is strictly positive if there is indication of a heart condition.

Logit models

Time cories

Variance and standard deviation

- The variance (resp., standard deviation) is computed by var() (resp., sd()).
- If the variable has NA (missing values), then var(), sd() return NA:

```
var(cleve$thal)
## [1] NA
sd(cleve$thal)
```

```
## [1] NA
```

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Timo carios

Variance

We can apply the function var() to a single variable or several of them; in the latter case, we obtain the variance-covariance matrix of the selected variables:

```
var(cleve[, c(1, 3, 5, 6)])
## age cp
```

```
## age cp chol fbs

## age 81.697 0.9037 97.787 0.3816

## cp 0.904 0.9218 3.595 -0.0137

## chol 97.787 3.5951 2680.849 0.1815

## fbs 0.382 -0.0137 0.181 0.1269
```

Introduction to R

Preliminary analysis

Statistica Inference

Linear regression

Logit models

Time series

Standard deviation of a set of variables

We have to vectorize the function sd() by means of apply():

```
apply(cleve[,11:13], 2, sd)
```

- The value 2 in the second parameter of the function apply() computes the standard deviation, sd, of each variable (column).
- The value 1 would compute the standard deviation of each row (observation).

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Time series

Count and remove NA's

```
Let's count them:
```

```
sum(is.na(cleve))
```

[1] 6

We can eliminate them (less than 2% of the observed values)

```
cleve <- na.omit(cleve)
sum(is.na(cleve))</pre>
```

[1] 0

Remark

R works in memory (RAM), so only the dataset **cleve** loaded in memory is changed. The file **cleve.csv** with the original observations is not changed (reproducibility in research).

Logit model:

Timo carios

Power calculation

Having rejected the null hypothesis, we compute the power of the test under the alternative

$$H_1$$
: $age.pos - age.neg = 2.5$

A power calculation needs four parameters, α , sd, n (sample size), δ (true difference in mean). It must also specify whether the test is one sided or two sided.

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Time series

Remark

If we need to estimate models with interactions, or quadratic terms (continuous variables), we need to use I(x1*x2) in the model definition.

For example, to estimate either model

$$math = \beta_0 + \beta_1 read + \beta_2 socst + \beta_3 socst^2 + u$$

 $math = \beta_0 + \beta_1 read + \beta_2 socst + \beta_3 socst \cdot read + u$

we have to define the model as either

or

Introduction to R(Studio

Data Types and Data Structure

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regression models

Logit models

Time series

Accuracy: Mean Absolute Percentage Error (MAPE)

The mean absolute percentage error (MAPE) is defined as

$$MAPE = \frac{1}{T} \sum_{i=1}^{I} \left| \frac{A_i - F_i}{A_i} \right|.$$

- MAPE can be interpreted as the average percentage error.
- Sometimes, MAPE can be very large, even though the forecast is reasonably good. If, e.g., $A_i \approx 10^{-3}$ and $|F_i A_i| \approx 10^{-1}$, entonces

$$\left|\frac{A_i - F_i}{A_i}\right| \approx 10^2$$

• If the forecast is exact, then MAPE = 0.

Statistica Inference

Linear regression models

Logit models

Time series

Plots: Leverage and influential observations

- The leverage in a linear regression can be computed using the projection matrix (F. Hayashi, 2000, *Econometrics*, Princeton University Press, pp. 21-23).
- The Cook's distance defined in the next slide can be often used as a measure of observaions with high leverage;
 Cook's distance can also be used to detect highly influential observations.
- In R, the <u>residual-leverage</u> plot draws a red, dashed line identifying observations with Cook's distance greater than .5.
- In R, observations with leverage greater than 1 are omitted with a warning; check Residual-Leverage plot in "Details" here,

Logit models

Time series

Goodness of fit

A measure of goodness of fit is a comparison of the estimated logit model to the null modelo

$$logit(diagnostic) = \beta_0$$

The comparison is done by the hypothesis test

 H_0 : The null model fits better the data

 H_1 : The logit model fits better the data

$$(\alpha = .05.)$$

Statistica Inference

Linear regression models

Logit models

Time series

Goodness of fit

The test statistics is the difference of deviations, which has χ^2 distribution, with df. null - df.residual degrees of freedom:

[1] 0.000322

Conclusion

The logit model better fit the data.

Time series

Let y_t be a stochastic process.

The idea of exponential smoothing is to compute the *one-step* ahead forecast, $\hat{y}_{T+1|T}$, as a weighted mean of the previous observed terms:

$$\widehat{y}_{T+1|T} = \alpha y_T + \alpha (1-\alpha) y_{T-1} + \cdots$$
$$= \alpha y_T + (1-\alpha) \widehat{y}_{T|T-1}, \qquad 0 \le \alpha < 1;$$

rearranging terms,

$$\widehat{y}_{t+1|t} = \alpha y_t + (1 - \alpha)\widehat{y}_{t|t-1},$$

Introduction to R

Lino AA Notarantonio (lino@tec.mx)

Introduction to R(Studio

Working with a Dataframe

Preliminary analysis

Statistica Inference

Linear regressior models

Logit models

Time series

which gives

$$\begin{split} \widehat{y}_{t+1|t} &= \alpha y_t + (1 - \alpha) \widehat{y}_{t|t-1} = \widehat{y}_{t|t-1} + \alpha (y_t - \widehat{y}_{t|t-1}) \\ &= \widehat{y}_{t|t-1} + \alpha e_t, \end{split}$$

where $e_t = y_t - \hat{y}_{t|t-1}$ is the forecast error.

The value α is estimated optimizing the errors squared.

The work by Holt & Winters allowed the inclusion of seasonal, s_t , and trending, b_t , terms, beside the level term, ℓ_t .

Holt-Winters Modeling (Additive model)

$$y_{t+h|t} = \ell_t + hb_t + s_{t-m+h_m^+}$$

$$\ell_t = \alpha(y_t - s_{t-m}) + (1 - \alpha)(\ell_{t-1} - b_{t-1})$$

$$b_t = \beta^*(\ell_t - \ell_{t-1}) + (1 - \beta^*)b_{t-1}$$

$$s_t = \gamma(y_t - \ell_{t-1} - b_{t-1}) + (1 - \gamma)s_{t-m}$$

where m denotes the seasonality period (per year) The symbol

$$h_m^+ = \lfloor (h-1) \mod(m) \rfloor + 1$$

makes sure that the estimation of the seasonality is the last year of the sample.

Forecast

logJJ.forecast8095 <forecast(logJJ.forecast, h=8)</pre>

- We use the first estimate, logJJ.forecast, as it is proven to be the better.
- The parameter h=8 will forecast the estimate eight periods in the future (two years).
- The forecast also plots a confidence interval (80%; 95% is the default).
